EP 0 840 342 B1

Description

[0001] This invention relates to a relay drive circuit for driving relays to turn on and off power supplied to loads from a power supply outputting a given voltage according to claims 1, 2, 4 and 7.

[0002] From DE-A-28 09 905, which describes the closest prior art, a circuit arrangement for holding a relay is known, wherein after the actuation of the relay by means of a threshold switch and by means of a logic equipment a first DC power source supplying the actuating current for the relay is switched off and a second DC power supply source supplying the hold current is switched on. This known circuit arrangement is characterized in that in dependence upon the current flowing through the relay coil a controller controls said current by means of a controllable resistor serially connected to the first current source. This controller can have, for example, a D behavior. Moreover this known circuit arrangement also comprises a switch amplifier, which is used for switching the first power supply source. The threshold switch and the controller are comprised of a common input transistor stage.

[0003] A further conventional circuit for driving various loads 2 of an automobile also uses relays. For example, as shown in Figure 13, the circuit comprises a coil RC of a relay RL connected at one end to a voltage output terminal of an in-car battery 1 and grounded at the other end via an operation switch SW and one of relay contacts RS connected to the voltage output terminal of the in-car battery 1 and the other grounded via loads 2.

[0004] When the operation switch SW is turned on and a voltage equal to or more than an actuating voltage required for actuating the relay contacts RS is applied to the coil RC, the relay contacts RS are actuated and conducted. On the other hand, when the operation switch SW is turned off and the voltage applied to the coil RC becomes equal to or less than a release voltage, the relay contacts RS are released and restored to a non-conduction state.

[0005] In an automobile, circuit parts of relays, fuses, connectors, etc., are mounted on an electric junction box intensively. Since the circuit parts generate heat, it is necessary to design so as not to exceed the heat resistance temperatures of the parts and the electric junction box.

[0006] However, in recent years, as the number of relays has been increased with an increase in in-car electrical components and relays have been placed at a high density with miniaturization of the relays, the effect of heat generation of the relays, namely, coils becomes large and the heat generation needs to be suppressed.

[0007] Generally, the relay actuating voltage is about 7-8 V, the relay release voltage is about 2-3 V, and the power supply voltage of the in-car battery is 12 V. Thus, the relay generates unnecessary heat as much as the voltage difference between the battery power supply voltage and the relay actuating voltage.

[0008] Then, as shown in Figure 14, a conventional circuit is known which comprises a resistor R connected to a coil RC of a relay RL in series for decreasing an applied voltage to the coil RC, thereby reducing the heating value of the relay RL.

[0009] A relay drive circuit is proposed in Japanese Patent Laid-Open No. Hei 8-55551 wherein a drive transistor for supplying an excitation current to a relay coil is operated in a region in which it is not completely turned on, thereby decreasing an applied voltage to the coil.

[0010] Although the conventional circuit shown in Figure 14 decreases the heating value of the coil RC of the relay RL, the resistor R generates heat, thus it is difficult to sufficiently decrease the heating value of the whole circuit.

[0011] Also in the conventional relay drive circuit described in Japanese Patent Laid-Open No. Hei B-55551, the reduction part of the coil application voltage is converted into heat by other circuit parts of transistors, etc., thus it is still difficult to sufficiently decrease the heating value of the whole circuit.

[0012] Furthermore, in the conventional relay drive circuit described in Japanese Patent Laid-Open No. Hei 8-55551, if the actuated relay contacts are restored to a release state for a reason such as vibration or impulse, the relay cannot again be placed in an actuation state unless an operation switch is once turned off, then on.

[0013] It is therefore an object of the present invention to provide a relay drive circuit that can decrease the coil heating value efficiently and hold relays in an actuation state reliably.

[0014] According to the present invention this object is solved by the features of the claims 1, 2, 4 and 7.

[0015] Improved embodiments of the inventive relay drive circuit result from the subclaims.

[0016] According to the invention, there is provided a relay drive circuit for controlling an excitation current supplied to relay coils with relay contacts placed between a reference power supply outputting a given voltage higher than a relay actuating voltage and a plurality of loads, thereby actuating or releasing the relay contacts, the relay drive circuit comprising a low-voltage power supply outputting a voltage lower than the given voltage and higher than the relay actuating voltage for supplying the excitation current to each relay coil from the low-voltage power supply.

[0017] According to the above configuration, an excitation current is supplied to each relay coil from the low-voltage power supply outputting a voltage lower than the given voltage output from the reference power supply and higher than the relay actuating voltage, whereby the relay contacts can be reliably actuated and the heating value from the coils can be reduced as compared with supply of the excitation current from the reference power supply.

[0018] According to the invention, there is provided a relay drive circuit for controlling an excitation current

supplied to relay coils with relay contacts placed between a reference power supply outputting a given voltage higher than a relay actuating voltage and a plurality of loads, thereby actuating or releasing the relay contacts, the relay drive circuit comprising a low-voltage power supply outputting a voltage lower than the given voltage and higher than a relay release voltage, time count means for counting the elapsed time since the actuation time of each relay, storage means for storing a preset time, and control means for supplying the excitation current from the reference power supply when each relay is actuated and supplying the excitation current from the reference power supply until the expiration of the preset time since the actuation time of each relay, then supplying the excitation current from the low-voltage power supply.

[0019] According to the configuration, when the relay contacts are actuated, the excitation current is supplied to the relay coil from the reference power supply outputting the given voltage, and the excitation current is supplied from the reference power supply until the expiration of the preset time since the actuation time of the relay contacts, then the excitation current is supplied from the low-voltage power supply outputting a voltage lower than the given voltage output from the reference power supply and higher than the relay release voltage, whereby the actuation state of the relay contacts is reliably maintained and the heating value from the coils is reduced as compared with continuous supply of the excitation current from the reference power supply.

[0020] The setup time is preset a little longer than the time taken until the relay contacts are actuated from the supply start time of the excitation current to the coil, whereby the relay contacts can be actuated reliably.

[0021] In the relay drive circuit as mentioned above, the low-voltage power supply outputs a voltage lower than the relay actuating voltage.

[0022] According to the configuration, the excitation current is supplied from the low-voltage power supply outputting a voltage lower than the relay actuating voltage, whereby the heating value from the coils is furthermore reduced.

[0023] According to the invention, there is provided a relay drive circuit for controlling an excitation current supplied to relay coils with relay contacts placed between a reference power supply outputting a given voltage higher than a relay actuating voltage and a plurality of loads, thereby actuating or releasing the relay contacts, the relay drive circuit comprising a low-voltage power supply outputting a voltage lower than the given voltage and higher than a relay release voltage, a reference voltage circuit for supplying an excitation current to each relay coil from the reference power supply, a low-voltage circuit for supplying an excitation current to each relay coil from the low-voltage power supply, and a stop control circuit for stopping the excitation current supply from the reference power supply after the expiration of a predetermined time since the actuation time

of the relay contacts after supply of the excitation current from the reference power supply.

[0024] According to the configuration, after the expiration of the predetermined time since the actuation time of the relay contacts after supply of the excitation current to each coil from the reference power supply, the excitation current supply from the reference power supply is stopped, then the excitation current is supplied from the low-voltage power supply outputting a voltage lower than the given voltage output from the reference power supply and higher than the relay release voltage, whereby the actuation state of the relay contacts is reliably maintained and the heating value from the coils is reduced as compared with continuous supply of the excitation current from the reference power supply.

[0025] The predetermined time is preset a little longer than the time taken until the relay contacts are actuated from the supply start time of the excitation current to the coil, whereby the relay contacts can be actuated reliably.

[0026] In the relay drive circuit as mentioned above, the low-voltage power supply outputs a voltage lower than the relay actuating voltage.

[0027] According to the configuration, the excitation current is supplied from the low-voltage power supply outputting a voltage lower than the relay actuating voltage, whereby the heating value from the coils is furthermore reduced.

[0028] Further, in the relay drive circuit as mentioned above, the stop control circuit comprises a capacitor and is built in the reference voltage circuit for lowering the applied voltage according to a predetermined time constant after the excitation current supply by voltage application to the coil from the reference power supply.

[0029] According to the configuration, the stop control circuit comprises a capacitor and is built in the reference voltage circuit for lowering the applied voltage according to a predetermined time constant after the excitation current supply by voltage application to the coil from the reference power supply, whereby a voltage higher than the relay actuating voltage is applied to the coil as long as a predetermined time and the relay contacts are actuated reliably.

[0030] Furthermore, according to the invention, there is provided a relay drive circuit for controlling an excitation current supplied to relay coils with relay contacts placed between a reference power supply outputting a given voltage higher than a relay actuating voltage and a plurality of loads, thereby actuating or releasing the relay contacts, the relay drive circuit comprising a low-voltage power supply outputting a voltage lower than the given voltage and higher than a relay release voltage, a reference voltage circuit for periodically supplying an excitation current as long as a preset time to each relay coil from the reference power supply when a relay actuation instruction is given, and a low-voltage circuit for supplying an excitation current to each relay coil from the low-voltage power supply when a relay actuation instruction is given.

[0031] According to the configuration, when a relay actuation instruction is given, the excitation current is periodically supplied as long as the preset time to each relay coil from the reference power supply outputting the given voltage and the excitation current is supplied to each relay coil from the low-voltage power supply outputting a voltage higher than the relay release voltage, whereby when the excitation current is supplied from the reference power supply, the relay contacts can be actuated and while the excitation current is supplied from the low-voltage power supply, the relay contacts are held in the actuation state. Resultantly, the heating value from the coils is reduced as compared with continuous supply of the excitation current from the reference power supply. If the actuated relay contacts are released for a reason such as vibration or impulse, when another excitation current is supplied from the reference power supply, the relay contacts are restored to the actuation state.

[0032] The setup time is preset a little longer than the time taken until the relay contacts are actuated from the supply start time of the excitation current to the coil, whereby the relay contacts can be actuated reliably.

[0033] In the relay drive circuit as mentioned above, the reference voltage circuit comprises an oscillation circuit for outputting a pulse signal having a pulse width of the setup time on a given period and a voltage supply circuit for supplying the excitation current from the reference power supply only while the pulse signal is output when a relay actuation instruction is given.

[0034] According to the configuration, when a pulse signal of a pulse width equal to the setup time is output on a given period and a relay actuation instruction is given, the excitation current is supplied from the reference power supply only while the pulse signal is output, whereby the excitation current is supplied from the reference power supply to the coil as long as the setup time every given period.

[0035] In the relay drive circuit as mentioned above, the low-voltage power supply outputs a voltage lower than the relay actuating voltage.

[0036] According to the configuration, the excitation current is supplied from the low-voltage power supply outputting a voltage lower than the relay actuating voltage, whereby the heating value from the coils is further more reduced.

BRIEF DESCRIPTION OF THE DRAWINGS

[0037] In the accompanying drawings:

Figure 1 is a circuit diagram to show a first embodiment of a vehicle load control circuit to which the invention is applied;

Figure 2 is a timing chart to show the state of each part in the first embodiment of the invention;

Figure 3 is a circuit diagram to show a second embodiment of a vehicle load control circuit to which the invention is applied;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

First Embodiment

[0038] Figure 1 is a circuit diagram to show a first embodiment of a vehicle load control circuit to which the invention is applied.

[0039] The vehicle load control circuit comprises an in-car battery (reference power supply) 1, loads 21, 22, 23, ... of lamps, door lock solenoid, etc., relays RL1, RL2, RL3, ..., switches SW1, SW2, SW3, ..., and a low-voltage power supply 3 for controlling a power supply from the in-car battery 1 to the loads 21, 22, 23, ... The relays RL1, RL2, RL3, ... and the low-voltage power supply 3 are placed in an electric junction box (not shown) disposed in a proper place in the vehicle.

[0040] The relay RL1 is made up of relay contacts RS1 placed between the in-car battery 1 and the load 21 and a coil RC1 placed between the low-voltage power supply 3 and the switch SW1. Likewise, the relay RL2 (RL3) is made up of relay contacts RS2 (RS3) placed between the in-car battery 1 and the load 22 (23) and a coil RC2 (RC3) placed between the low-voltage power supply 3 and the switch SW2 (SW3).

[0041] Relay actuating voltage V_S , namely, coil application voltage at which the relay contacts are actuated is about 7-8 VDC. Relay release voltage V_R , namely, coil application voltage at which the relay contacts are released is about 2-3 VDC. Output voltage of the in-car battery 1, V_B , is a value higher than the relay actuating

voltage V_S (in the embodiment, 12 VDC).

[0042] The switches SW1, SW2, SW3, ... are switches such as operation switches operated by the vehicle user and semiconductor switching elements turned on/off in response to the detection result of a sensor (not shown); one of switch contacts is connected to the coil RC1 (RC2, RC3) and the other is grounded.

[0043] The low-voltage power supply 3 is made of a switching power supply circuit made of a DC-DC converter using a switching transistor (not shown). It switches the output voltage V_B of the in-car battery 1 applied to a primary winding by the switching transistor, rectifies and smooths a voltage induced on a secondary winding, and outputs voltage V_A . The output voltage V_A is $V_B > V_A > V_S$ and is set to a value close to the actuating voltage V_S (in the embodiment, 10 V).

[0044] The operation of the vehicle load control circuit will be discussed with Figure 2, which is a timing chart to show the state of each part in the first embodiment.

[0045] When the switch SW1 is turned on, the output voltage V_A of the low-voltage power supply 3 slightly higher than the actuating voltage V_S is applied to the coil RC1 of the relay RL1, thus turning on the relay contacts RS. The relay RL2 (RL3) also operates in similar manner to that described here.

[0046] Thus, according to the first embodiment, the vehicle load control circuit comprises the low-voltage power supply 3 outputting the voltage V_A lower than the output voltage V_B of the in-car battery 1 and higher than the relay actuating voltage V_S in addition to the in-car battery 1 and applies the output voltage V_A of the low-voltage power supply 3 to the coil RC1, ... of the relay RL1, ..., so that it can reduce the heating value from the coil RC1, ... as compared with application of the output voltage V_B of the in-car battery 1.

[0047] The switching power supply circuit having a small heating value is used as the low-voltage power supply 3, whereby the heat generation of the whole circuit can be decreased.

[0048] The single low-voltage power supply 3 is used to drive a plurality of relays, whereby the heating value can be most decreased.

Second Embodiment

[0049] Figure 3 is a circuit diagram to show a second embodiment of a vehicle load control circuit to which the invention is applied. Parts identical with or similar to those previously described with reference to Figure 1 are denoted by the same reference numerals in Figure 3.

[0050] As shown in Figure 3, the second embodiment comprises a low-voltage power supply 30 in place of the low-voltage power supply 3 of the first embodiment and connection switch circuits 41, 42, 43, ... A coil RC1 (RC2, RC3) of a relay RL1 (RL2, RL3) is connected at one end to the connection switch circuit 41 and is grounded at the other end.

[0051] The connection switch circuit 41 (42, 43) comprises a contact section 41a (42a, 43a) placed between one end of the coil RC1 (RC2, RC3) and an in-car battery 1, a contact section 41b (42b, 43b) placed between one end of the coil RC1 (RC2, RC3) and the low-voltage power supply 30, and a diode D1 (D2, D3) forward connected from the contact section 41b (42b, 43b) to connection point X between the contact section 41b (42b, 43b) and the connection point X.

[0052] For example, the contact sections 41a and 41b are made of semiconductor switching elements, etc., controlled by a control circuit (not shown) and are actuated at the timing as shown in Figure 4 (described later).

[0053] The low-voltage power supply 30 is made of a switching power supply circuit made of a DC-DC converter using a switching transistor (not shown). It switches output voltage V_B of the in-car battery 1 applied to a primary winding by the switching transistor, rectifies and smooths a voltage induced on a secondary winding, and outputs voltage V_E . The output voltage V_E is ($V_B > V_S > V_E > V_R$) and is set to a value close to release voltage V_R (in the embodiment, 5 V).

[0054] Next, the operation of the vehicle load control circuit will be discussed with Figure 4, which is a timing chart to show the state of each part in the second embodiment.

[0055] When the switch SW1 is turned on, first the contact section 41a is turned on and the output voltage V_B of the in-car battery 1 higher than the actuating voltage V_S is applied to the coil RC1 of the relay RL1, turning on relay contacts RS1. Next, the contact section 41b is turned on, then the contact section 41a is turned off and the output voltage V_E of the low-voltage power supply 30 slightly higher than the release voltage V_R is applied, thus the relay contacts RS1 remain on. The relay RL2 (RL3) also operates in similar manner to that described here.

[0056] Thus, according to the second embodiment, the vehicle load control circuit comprises the low-voltage power supply 30 outputting the voltage V_E lower than the output voltage V_B of the in-car battery 1 and slightly higher than the relay release voltage V_R in addition to the in-car battery 1 and applies the output voltage V_B of the in-car battery 1 to the coil RC1, ... of the relay RL1, ... for actuating the relay contacts, then applies the output voltage V_E of the low-voltage power supply 30, so that it can reliably actuate the relay contacts and reduce the heating value from the coils as compared with continuation of application of the output voltage V_B of the in-car battery 1.

[0057] The switching power supply circuit having a small heating value is used as the low-voltage power supply 30, whereby the heat generation of the whole circuit can be decreased.

[0058] The single low-voltage power supply 30 is used to drive a plurality of relays, whereby the heating value can be most decreased.

Third Embodiment

[0059] Figure 5 is a circuit diagram to show a third embodiment of a vehicle load control circuit to which the invention is applied. Parts identical with or similar to those previously described with reference to Figure 3 are denoted by the same reference numerals in Figure 5.

[0060] The third embodiment provides a specific circuit configuration of the connection switch circuit 41 of the second embodiment, as shown in Figure 5. The connection switch circuit 41 comprises a CPU 5, a diode D1, transistors Q11-Q14, and resistors R10-R16.

[0061] Loads 22, 23, ..., relays RL2, RL3, ..., switches SW2, SW3, ..., and connection switch circuits 42, 43, ... are not shown in Figure 5.

[0062] The CPU 5 has output terminals P1 and P2, an input terminal P3, a power supply terminal V_{DD} connected to a voltage output terminal of a low-voltage power supply 30, a ground terminal GND grounded, and a ROM 51 and controls the operation of the connection switch circuit 41 in response to an output signal from the output terminal P1, P2 as described later. The CPU 5 detects the level of a voltage signal input to the input terminal P3, thereby determining whether a switch SW1 is on or off. The ROM 51 stores preset time T.

[0063] First, the circuit configuration between the CPU 5 and an in-car battery 1 will be discussed. The output terminal P1 of the CPU 5 is connected to a base of the transistor Q12 via the resistor R11. An emitter of the transistor Q12 is grounded and a collector of the transistor Q12 is connected to a base and an emitter of the transistor Q11 via the resistors R12 and R13 respectively. The emitter of the transistor Q11 is connected to a voltage output terminal of the in-car battery 1. A collector of the transistor Q11 is connected to one end of a coil RC1 of a relay RL1.

[0064] Next, the circuit configuration between the CPU 5 and the low-voltage power supply 30 will be discussed. It is similar to the circuit configuration between the CPU 5 and the in-car battery 1. That is, the output terminal P2 of the CPU 5 is connected to a base of the transistor Q14 via the resistor R14. An emitter of the transistor Q14 is grounded and a collector of the transistor Q14 is connected to a base and an emitter of the transistor Q13 via the resistors R15 and R16 respectively. The emitter of the transistor Q13 is connected to the voltage output terminal of the low-voltage power supply 30. A collector of the transistor Q13 is connected to an anode of the diode D1 and a cathode of the diode D1 is connected to one end of the coil RC1 of the relay RL1.

[0065] Next, the miscellaneous circuit configuration will be discussed. One contact of the switch SW1 is connected to the input terminal P3 of the CPU 5 and the voltage output terminal of the low-voltage power supply 30 via the resistor R10 and the other contact of the switch SW1 is grounded, whereby when the switch SW1 is off, a high signal is input to the input terminal P3 and

when the switch SW1 is turned on, a low signal is input to the input terminal P3, so that the CPU can determine whether the switch SW1 is on or off.

[0066] Next, the operation of the vehicle load control circuit will be discussed with Figure 6, which is a timing chart to show the state of each part in the third embodiment.

[0067] When the switch SW1 is turned on, first a high signal is output from the output terminal P1 of the CPU 5 and the transistor Q12 is turned on, thereby turning on the transistor Q11, applying output voltage V_B of the in-car battery 1 higher than actuating voltage V_S to the coil RC1 of the relay RL1, turning on relay contacts RS1.

[0068] At this time, the diode D1 blocks a current flowing into the transistor Q13 from the transistor Q11.

[0069] Next, a high signal is output from the output terminal P2 of the CPU 5 and the transistor Q14 is turned on, thereby turning on the transistor Q13. The CPU 5 counts the elapsed time since the high signal was output from the output terminal P1. After the expiration of the setup time T, the output signal from the output terminal 1 of the CPU 5 is restored to a low signal, whereby output voltage V_E of the low-voltage power supply 30 slightly higher than release voltage V_R is applied to the coil RC1 of the relay RL1, so that the relay contacts RS1 are held on.

[0070] If the setup time T is preset a little longer than the time required until the relay contacts RS1 are actuated from the start of application of the output voltage V_B of the in-car battery 1, the relay contacts RS1 can be actuated reliably.

[0071] The connection switch circuit 42, 43 (not shown) may adopt a similar circuit configuration to that of the connection switch circuit 41 and can share the in-car battery 1, the low-voltage power supply 30, and the CPU 5.

[0072] Thus, according to the third embodiment, the vehicle load control circuit comprises the low-voltage power supply 30 outputting the voltage V_E lower than the output voltage V_B of the in-car battery 1 and slightly higher than the relay release voltage V_R in addition to the in-car battery 1 and applies the output voltage V_B of the in-car battery 1 to the coil RC1 of the relay RL1 for turning on the relay contacts, then applies the output voltage V_E of the low-voltage power supply 30, so that it can reliably actuate the relay contacts and reduce the heating value from the coils as compared with continuation of application of the output voltage V_B of the in-car battery 1, as in the second embodiment.

[0073] The switching power supply circuit having a small heating value is used as the low-voltage power supply 30, whereby the heat generation of the whole circuit can be decreased.

[0074] The low-voltage power supply 30 is shared as a power supply of 5-V circuit parts of the CPU 5, etc., whereby an increase in the number of parts can be suppressed and the heating value can be decreased.

[0075] The low-voltage power supply 30 may be dis-

posed in a plurality of electric junction boxes in the vehicle for connection to a plurality of relays. It may also be disposed in one place in the vehicle for connection to all relays. In this case, the single low-voltage power supply 30 is used to drive all relays, whereby the heating value can be most decreased.

[0076] The low-voltage power supply 3, 30 may be made of a primary or secondary battery of the output voltage V_A , V_E . To use a secondary battery, the low-voltage power supply may be able to be charged by the in-car battery 1.

[0077] We have discussed the embodiments of applying the invention to the vehicle load control circuits, but the invention is not limited to them and may be applied to general relay drive circuits.

[0078] As we have discussed, according to the invention, the excitation current is supplied to each relay coil from the low-voltage power supply outputting a voltage lower than the given voltage higher than the relay actuating voltage output from the reference power supply and higher than the relay actuating voltage, so that the relay contacts can be reliably actuated and the heating value from the coils can be reduced as compared with supply of the excitation current from the reference power supply.

[0079] When the relay contacts are actuated, the excitation current is supplied to the relay coil from the reference power supply outputting the given voltage higher than the relay actuating voltage, and the excitation current is supplied from the reference power supply until the expiration of the preset time since the actuation time of the relay contacts, then the excitation current is supplied from the low-voltage power supply outputting a voltage lower than the given voltage output from the reference power supply and higher than the relay release voltage, so that the actuation state of the relay contacts can be reliably maintained and the heating value from the coils can be reduced as compared with continuous supply of the excitation current from the reference power supply.

[0080] The excitation current is supplied from the low-voltage power supply outputting a voltage lower than the relay actuating voltage, whereby the heating value from the coils can be furthermore reduced.

Fourth Embodiment

[0081] Figure 7 is a circuit diagram to show a fourth embodiment of a vehicle load control circuit to which the invention is applied.

[0082] The vehicle load control circuit comprises an in-car battery (reference power supply) 1, loads 21, 22, ... of lamps, door lock solenoid, etc., relays RL1, RL2, ..., switches SW1, SW2, ..., a low-voltage power supply 3, and connection switch circuits 41, 42, ... for controlling a power supply from the in-car battery 1 to the loads 21, 22, ...

[0083] The relays RL1, RL2, ..., the low-voltage power

supply 3, and the connection switch circuits 41, 42, ... are placed in an electric junction box (not shown) disposed in a proper place in the vehicle.

[0084] The relay RL1 is made up of relay contacts RS1 placed between the in-car battery 1 and the load 21 and a coil RC1 placed between the connection switch circuit 41 and ground.

[0085] Relay actuating voltage V_S , namely, coil application voltage at which the relay contacts are actuated is about 7-8 VDC. Relay release voltage V_R , namely, coil application voltage at which the relay contacts are released is about 2-3 VDC. Output voltage of the in-car battery 1, V_B , is a value higher than the actuating voltage V_S (in the embodiment, 12 VDC). The connection switch circuits 41, 42, ... have a similar configuration.

[0086] The switches SW1, SW2, ... are switches such as operation switches operated by the vehicle user and semiconductor switching elements turned on/off in response to the detection result of a sensor (not shown); one of switch contacts is connected to the connection switch circuit 41, 42 and the other is connected to a voltage output terminal of the in-car battery 1.

[0087] The low-voltage power supply 3 is made of a switching power supply circuit made of a DC-DC converter using a switching transistor (not shown). It switches the output voltage V_B of the in-car battery 1 applied to a primary winding by the switching transistor, rectifies and smooths a voltage induced on a secondary winding, and outputs voltage V_E . The output voltage V_E is ($V_B > V_S > V_E > V_R$) and is set to a value close to the release voltage V_R (in the embodiment, 5 V).

[0088] The connection switch circuit 41 comprises a transistor Q11, diodes D11 and D12, resistors R11 and R12, and a capacitor C11 and functions as a reference voltage circuit, a low-voltage circuit, and a stop control circuit.

[0089] The transistor Q11 has a collector connected to a voltage output terminal of the low-voltage power supply 3, a base connected to one contact of the switch SW1 via the resistor R11, and an emitter connected to an anode of the diode D11.

[0090] A cathode of the diode 11 is connected to the coil RC1 of the relay RL1, one contact of the switch SW1 via the capacitor C11, and a cathode of the diode D12.

[0091] An anode of the diode D12 is grounded and one contact of the switch SW1 is grounded via the resistor R12. The diode D12 is provided to bypass a counter-electromotive force generated at the coil RC1 when the relay RL1 is turned off.

[0092] Next, the operation of the vehicle load control circuit will be discussed with Figure 8, which is a timing chart to show the state of each part in the fourth embodiment.

[0093] When the switch SW1 is turned on, first the output voltage V_B of the in-car battery 1 is applied to the coil RC1 of the relay RL1, thus application voltage V_L to the coil RC1 becomes higher than the actuating voltage V_S , turning on the relay contacts RS1.

[0094] At the same time, a base current is supplied through the resistor R11 and the transistor Q11 is turned on, whereby anode voltage V_P of the diode D11 becomes equal to the output voltage V_E of the low-voltage power supply 3.

[0095] At this time, the diode D11 blocks current flowing into the anode from the cathode of the diode D11.

[0096] Next, as the capacitor C11 is charged by the output voltage V_B of the in-car battery 1, the application voltage V_L to the coil RC1 lowers. However, when the voltage falls below the anode voltage V_P of the diode D11, the output voltage V_E of the low-voltage power supply 3 slightly higher than the release voltage V_R is applied to the coil RC1 via the diode D11, so that the relay contacts RS1 are held on.

[0097] When the switch SW1 is turned off, charges accumulated in the capacitor C11 are discharged through the resistor R12 and the charge voltage lowers, whereby the transistor Q11 is turned off and the application voltage V_L to the coil RC1 falls below the release voltage V_R . At this time, the relay contacts RS1 are turned off.

[0098] Thus, according to the fourth embodiment, the vehicle load control circuit comprises the low-voltage power supply 3 outputting the voltage V_E lower than the output voltage V_B of the in-car battery 1 and slightly higher than the relay release voltage V_R in addition to the in-car battery 1 and applies the output voltage V_B of the in-car battery 1 to each relay coil for turning on the relay contacts, then applies the output voltage V_E of the low-voltage power supply 3, so that it can reliably actuate the relay contacts and reduce the heating value from the coils as compared with continuation of application of the output voltage V_B of the in-car battery 1.

[0099] The switching power supply circuit having a small heating value is used as the low-voltage power supply 3, whereby the heat generation of the whole circuit can be decreased.

[0100] The single low-voltage power supply 3 is used to drive a plurality of relays, whereby the heating value can be most decreased.

Fifth Embodiment

[0101] Figure 9 is a circuit diagram to show a fifth embodiment of a vehicle load control circuit to which the invention is applied. Parts identical with or similar to those previously described with reference to Figure 6 are denoted by the same reference numerals in Figure 9.

[0102] As shown in Figure 9, the fifth embodiment comprises connection switch circuits 51, 52, ... in place of the connection switch circuits 41, 42, ... of the fourth embodiment. The connection switch circuits 51, 52 have a similar configuration.

[0103] The connection switch circuit 51 comprises a transistor Q111, a diode D111, resistors R111-R113, and a capacitor C111 and functions as a reference voltage

circuit, a low-voltage circuit, and a stop control circuit.

[0104] The transistor Q111 has a collector connected to a voltage output terminal of an in-car battery 1, a base connected to the voltage output terminal of the in-car battery 1 via the resistors R111 and R112, and an emitter connected to a cathode of the diode D111 and one end of a coil RC1 of a relay RL1. An anode of the diode D111 is connected to a voltage output terminal of a low-voltage power supply 3.

[0105] The connection point of the resistors R111 and R112 is connected via the resistor R113 to the other end of the coil RC1 of the relay RL1 and one contact of a switch SW1 and is grounded via the capacitor C111. The other contact of the switch SW1 is grounded.

[0106] Next, the operation of the vehicle load control circuit will be discussed with Figure 10, which is a timing chart to show the state of each part in the fifth embodiment.

[0107] When the switch SW1 is off, a base current is supplied via the resistors R112 and R111 to the transistor Q111, which is on, and the capacitor C111 is charged.

[0108] Therefore, voltage at one end of the coil RC1, namely, emitter voltage V_P of the transistor Q111, voltage V_Q at the other end of the coil RC1, and charge voltage V_C of the capacitor C111 are all equal to output voltage V_B of the in-car battery 1. Thus, application voltage V_L to the coil RC1 of the relay RL1 is 0.

[0109] At this time, the diode D111 blocks current flowing into the anode from the cathode of the diode D111.

[0110] When the switch SW1 is turned on, first the coil RC1 is grounded at the other end, thus the voltage V_Q lowers to 0. On the other hand, charges of the capacitor C111 are discharged through the resistor R113 and the switch SW1. However, while the charge voltage V_C lowers to a predetermined level, the transistor Q111 continues on.

[0111] Therefore, while the transistor Q111 is on, the application voltage V_L to the coil RC1 of the relay RL1 becomes equal to the output voltage V_B of the in-car battery 1 higher than actuating voltage V_S , whereby relay contacts RS1 are turned on.

[0112] Next, when the charge voltage V_C lowers to the predetermined level and the transistor Q111 is turned off, the application voltage V_L to the coil RC1 of the relay RL1 becomes equal to output voltage V_E of the low-voltage power supply 3, thus the relay contacts RS1 are held on.

[0113] When the switch SW1 is turned off, the voltages V_P , V_Q , and V_C are restored to the former level, namely, the output voltage V_B of the in-car battery 1, thus the relay contacts RS1 are turned off. At this time, voltage is temporarily reversely applied, as shown in Figure 4, by a counter-electromotive force generated at the coil RC1.

[0114] The capacity value of the capacitor C111 and the resistance value of the resistor R113 may be set so that the transistor Q111 continues on only until the relay contacts RS1 are actuated reliably.

[0115] Thus, according to the fifth embodiment, the vehicle load control circuit comprises the low-voltage power supply 3 outputting the voltage V_E lower than the output voltage V_B of the in-car battery 1 and slightly higher than the relay release voltage V_R in addition to the in-car battery 1 and applies the output voltage V_B of the in-car battery 1 to the relay coil for turning on the relay contacts, then applies the output voltage V_E of the low-voltage power supply 3, so that the effects similar to those of the fourth embodiment can be produced.

[0116] The low-voltage power supply 3 may be disposed in a plurality of electric junction boxes in the vehicle for connection to a plurality of relays. It may also be disposed in one place in the vehicle for connection to all relays. In this case, the single low-voltage power supply 3 is used to drive all relays, whereby the heating value can be most decreased.

[0117] The low-voltage power supply 3 may be shared as a power supply of 5-V circuit parts of an electronic controller, etc., whereby an increase in the number of parts can be suppressed and the heating value can be decreased.

[0118] The low-voltage power supply 3 may be made of a primary or secondary battery of the output voltage V_E . To use a secondary battery, the low-voltage power supply may be able to be charged by the in-car battery 1.

[0119] We have discussed the embodiments of applying the invention to the vehicle load control circuits, but the invention is not limited to them and may be applied to general relay drive circuits.

[0120] As we have discussed, according to the invention, after the expiration of the predetermined time since the actuation time of the relay contacts after supply of the excitation current to each coil from the reference power supply outputting a given voltage higher than the actuating voltage, the excitation current supply from the reference power supply is stopped, then the excitation current is supplied from the low-voltage power supply outputting a voltage lower than the given voltage output from the reference power supply and higher than the relay release voltage. Thus, the actuation state of the relay contacts can be reliably maintained and the heating value from the coils can be reduced as compared with continuous supply of the excitation current from the reference power supply.

[0121] The excitation current is supplied from the low-voltage power supply outputting a voltage lower than the relay actuating voltage, whereby the heating value from the coils can be furthermore reduced.

[0122] The stop control circuit comprises a capacitor and is built in the reference voltage circuit for lowering the applied voltage according to a predetermined time constant after the excitation current supply by voltage application to the coil from the reference power supply, whereby a voltage higher than the relay actuating voltage is applied to the coil as long as a predetermined time and the relay contacts can be actuated reliably.

Sixth Embodiment

[0123] Figure 11 is a circuit diagram to show a sixth embodiment of a vehicle load control circuit to which the invention is applied.

[0124] The vehicle load control circuit comprises an in-car battery (reference power supply) 1, loads 21, 22, ... of lamps, door lock solenoid, etc., relays RL1, RL2, ..., switches SW1, SW2, ..., a low-voltage power supply 3, connection switch circuits 41, 42, ..., and an oscillation circuit 5 for controlling a power supply from the in-car battery 1 to the loads 21, 22, ...

[0125] The relays RL1, RL2, ..., the low-voltage power supply 3, and the connection switch circuits 41, 42, ... are placed in an electric junction box disposed in a proper place in the vehicle. The connection switch circuits 41, 42, ... have a similar configuration.

[0126] The relay RL1 is made up of relay contacts RS1 placed between the in-car battery 1 and the load 21 and a coil RC1 placed between the connection switch circuit 41 and the switch SW1.

[0127] Relay actuating voltage V_S , namely, coil application voltage at which the relay contacts are actuated is about 7-8 VDC. Relay release voltage V_R , namely, coil application voltage at which the relay contacts are released is about 2-3 VDC. Output voltage of the in-car battery 1, V_B , is a value higher than the actuating voltage V_S (in the embodiment, 12 VDC).

[0128] The switches SW1, SW2, ... are switches such as operation switches operated by the vehicle user and semiconductor switching elements turned on/off in response to the detection result of a sensor (not shown); one of switch contacts is connected to one end of the coil RC1 of the relay RL1 and the other is grounded.

[0129] The low-voltage power supply 3 is made of a switching power supply circuit made of a DC-DC converter using a switching transistor (not shown). It switches the output voltage V_B of the in-car battery 1 applied to a primary winding by the switching transistor, rectifies and smooths a voltage induced on a secondary winding, and outputs voltage V_E . The output voltage V_E is ($V_B > V_S > V_E > V_R$) and is set to a value close to the release voltage V_R (in the embodiment, 5 V).

[0130] The oscillation circuit 5 outputs a pulse signal of a predetermined pulse width on a given period from an oscillation output terminal, as shown in Figure 12 (described later). The connection switch circuit 41 comprises transistors Q11 and Q12, diodes D11 and D12, and resistors R11-R13.

[0131] The oscillation output terminal of the oscillation circuit 5 is connected to a base of the transistor Q11 via the resistor R11. An emitter of the transistor Q11 is grounded and a collector is connected to a base and an emitter of the transistor Q12 via the resistors R12 and R13 respectively.

[0132] The emitter of the transistor Q12 is connected to a voltage output terminal of the in-car battery 1 and a collector of the transistor Q12 is connected to an an-

ode of the diode D11. A cathode of the diode D11 is connected to a cathode of the diode D12 and one end of the coil RC1. An anode of the diode D12 is connected to a voltage output terminal of the low-voltage power supply 3.

[0133] Next, the operation of the vehicle load control circuit will be discussed with Figure 12, which is a timing chart to show the state of each part in the embodiment.

[0134] A pulse voltage signal of a predetermined pulse width T_1 is output on a given period T_0 from the oscillation output terminal of the oscillation circuit 5. When the pulse voltage signal is high, the transistor Q11 is turned on, thereby turning on the transistor Q12, and cathode voltage V_K of the diode D11 becomes equal to the output voltage V_B of the in-car battery 1 higher than the relay actuating voltage V_S . At this time, the diode D12 blocks current flowing into the anode.

[0135] On the other hand, when the pulse voltage signal from the oscillation circuit 5 is low, the transistors Q11 and Q12 are turned off. Thus, the cathode voltage V_K becomes equal to the output voltage V_E of the low-voltage power supply 3 lower than the relay actuating voltage V_S . At this time, the diode D11 blocks current flowing into the anode.

[0136] Thus, the cathode voltage V_K becomes a voltage periodically matching the output voltage V_B of the in-car battery 1 and the output voltage V_E of the low-voltage power supply 3 in synchronization with the pulse voltage signal of the oscillation circuit 5, as shown in Figure 12.

[0137] Therefore, if the switch SW1 is turned on while the pulse voltage signal from the oscillation circuit 5 is low, an excitation current is supplied to the coil RC1 and application voltage V_L to the coil RC1 of the relay RL1 becomes equal to the output voltage V_E of the low-voltage power supply 3. At this time, the application voltage V_L is lower than the relay actuating voltage V_S , thus the relay contacts RS1 are not turned on.

[0138] Next, when the pulse voltage signal from the oscillation circuit 5 goes high, the application voltage V_L to the coil RC1 becomes equal to the output voltage V_B of the in-car battery 1 higher than the relay actuating voltage V_S , whereby the relay contacts RS1 are turned on.

[0139] After this, if the pulse voltage signal from the oscillation circuit 5 goes low, the application voltage V_L to the coil RC1 becomes equal to the output voltage V_E of the low-voltage power supply 3 slightly higher than the release voltage V_R , thus the relay contacts RS1 are held on.

[0140] When the switch SW1 is turned off, the excitation current supply to the coil RC1 is stopped and the relay contacts RS1 are turned off.

[0141] Thus, according to the sixth embodiment, the vehicle load control circuit comprises the low-voltage power supply 3 outputting the voltage V_E lower than the output voltage V_B of the in-car battery 1 and slightly higher than the relay release voltage V_R in addition to

the in-car battery 1 and applies the output voltage V_B of the in-car battery 1 to the relay coil periodically when the switch SW1 is on and the output voltage V_E of the low-voltage power supply 3 while the switch SW1 is not on, so that it can reliably turn on the relay contacts when the output voltage V_B of the in-car battery 1 is applied first after the switch SW1 is turned on. Then, the output voltage V_B is applied periodically and otherwise, the output voltage V_E of the low-voltage power supply 3 is applied, whereby the heating value from the coils can be reduced as compared with continuation of application of the output voltage V_B of the in-car battery 1.

[0142] The switching power supply circuit having a small heating value is used as the low-voltage power supply 3, whereby the heat generation of the whole circuit can be decreased.

[0143] The single low-voltage power supply 3 is used to drive a plurality of relays, whereby the heating value can be most decreased.

[0144] If the relay contacts RS1 are released for a reason such as vibration or impulse while the relay contacts RS1 are actuated and the output voltage V_E of the low-voltage power supply 3 is applied, the output voltage V_B of the in-car battery 1 is applied on the period T_0 , so that the relay contacts RS1 can be restored to the actuation state reliably within the period T_0 .

[0145] The pulse width T_1 of the pulse voltage signal output from the oscillation circuit 5 may be set to a value at which the relay contacts RS1 are reliably actuated. To rapidly restore the relay contacts to the actuation state if the relay contacts are released regardless of the actuation state, the period T_0 may be set to a short value; to furthermore reduce the heating value from the coils, the period T_0 may be set to a long value. For example, T_1 can be set to 10 msec and T_0 can be set to 100 msec.

[0146] The low-voltage power supply 3 may be disposed in a plurality of electric junction boxes in the vehicle for connection to a plurality of relays. It may also be disposed in one place in the vehicle for connection to all relays. In this case, the single low-voltage power supply 3 is used to drive all relays, whereby the heating value can be most decreased.

[0147] The low-voltage power supply 3 may be shared as a power supply of 5-V circuit parts of an electronic controller, etc., whereby an increase in the number of parts can be suppressed and the heating value can be decreased.

[0148] The low-voltage power supply 3 may be made of a primary or secondary battery of the output voltage V_E . To use a secondary battery, the low-voltage power supply may be able to be charged by the in-car battery 1.

[0149] We have discussed the embodiments of applying the invention to the vehicle load control circuits, but the invention is not limited to them and may be applied to general relay drive circuits.

[0150] As we have discussed, according to the invention, when a relay actuation instruction is given, the ex-

citation current is periodically supplied as long as the preset time to each relay coil from the reference power supply outputting the given voltage higher than the relay actuating voltage and the excitation current is supplied to each relay coil from the low-voltage power supply outputting a voltage higher than the relay release voltage. Thus, when the excitation current is supplied from the reference power supply, the relay contacts can be actuated and while the excitation current is supplied from the low-voltage power supply, the relay contacts can be held in the actuation state. Resultantly, the heating value from the coils can be reduced as compared with continuous supply of the excitation current from the reference power supply. If the actuated relay contacts are released for a reason such as vibration or impulse, when another excitation current is supplied from the reference power supply, the relay contacts can be restored to the actuation state.

[0151] When a pulse signal of a pulse width equal to the setup time is output on a given period and a relay actuation instruction is given, the excitation current is supplied from the reference power supply only while the pulse signal is output, whereby the excitation current can be reliably supplied from the reference power supply to the coil as long as the setup time every given period.

[0152] The excitation current is supplied from the low-voltage power supply outputting a voltage lower than the relay actuating voltage, whereby the heating value from the coils can be furthermore reduced.

Claims

1. A relay drive circuit for controlling an excitation current supplied to relay coils (RC1, RC2, RC3), comprising a reference power supply (1) and a low-voltage power supply (3; 30) outputting a voltage lower than the given reference voltage (V_B), **characterized in that**
 - a) the relay contacts (RS1, RS2, RS3) are placed between said reference power supply (1) and a plurality of loads (21, 22, 23); and
 - b) said low-voltage power supply (3; 30) outputs a voltage (V_A) lower than the given reference voltage (V_B) and higher than the relay actuating voltage for supplying the excitation current to each relay coil from said low-voltage power supply (3; 30).
2. A relay drive circuit for controlling an excitation current supplied to relay coils (RC1, RC2, RC3), comprising a reference power supply (1) and a low-voltage power supply (30) outputting a voltage lower than the given reference voltage (V_B), **characterized in that** a relay drive circuit is provided, which comprises:

- 1) a low-voltage power supply (30), outputting a voltage lower than the given voltage and higher than a relay release voltage;
- 2) time count means (CPU 5) for counting elapsed time since the actuation time of each relay;
- 3) storage means (ROM 51) for storing a preset time (T); and
- 4) control means for supplying the excitation current from the reference power supply (1) when each relay is actuated and supplying the excitation current from the reference power supply (1) until expiration of the preset time (T) since the actuation time of each relay, then supplying the excitation current from said low-voltage power supply (30).

3. The relay drive circuit according to claim 2, wherein said low-voltage power supply (30) outputs a voltage lower than the relay actuating voltage.

4. A relay drive circuit for controlling an excitation current supplied to relay coils (RC1, RC2, RC3), comprising a reference power supply (1) and a low-voltage power supply (30) outputting a voltage lower than the given reference voltage (V_B), **characterized in that** a relay drive circuit is provided, which comprises:

- 1) a low-voltage power supply (30) outputting a voltage lower than the given voltage and higher than a relay release voltage;
- 2) a reference voltage circuit (41; Q11, D11, D12, R11, R12, C11) for supplying an excitation current to each relay coil from the reference power supply;
- 3) a low-voltage circuit for supplying an excitation current to each relay coil, from said low-voltage power supply (30); and
- 4) a stop control circuit (41; Q11, D11, D12, R11, R12, C11) for stopping the excitation current supply from the reference power supply (1) after expiration of a predetermined time since the actuation time of the relay contacts after supply of the excitation current from the reference power supply (1).

5. The relay drive circuit as claimed in claim 4, wherein said low-voltage power supply (30) outputs a voltage lower than the relay actuating voltage.

6. The relay drive circuit as claimed in claim 4, wherein said stop control circuit comprises a capacitor (C11) and is built in said reference voltage circuit for lowering applied voltage according to a predetermined time constant after excitation current supply by voltage application to the coil from the reference power supply (1).

7. A relay drive circuit for controlling an excitation current supplied to relay coils (RC1, RC2, RC3), comprising a reference power supply (1) and a low-voltage power supply (30) outputting a voltage lower than the given reference voltage (V_B), **characterized in that** a relay drive circuit is provided, which comprises:

1) a low-voltage power supply (30) outputting a voltage lower than the given voltage and higher than a relay release voltage;
 2) a reference voltage circuit (51; Q111, D111, R111-R113, C111) for periodically supplying an excitation current as long as a preset time to each relay coil from the reference power supply when a relay actuation instruction is given; and
 3) a low-voltage circuit for supplying an excitation current to each relay coil from said low-voltage power supply (30) when a relay actuation instruction is given.

8. The relay drive circuit as claimed in claim 7, wherein said reference voltage circuit comprises:

an oscillation circuit (5) for outputting a pulse signal having a pulse width of the setup time on a given period; and
 a voltage supply circuit for supplying the excitation current from the reference power supply (1) only while the pulse signal is output when a relay actuation instruction is given.

9. The relay drive circuit as claimed in claim 7, wherein said low-voltage power supply (30) outputs a voltage lower than the relay actuating voltage.

Patentansprüche

1. Relaisreiberschaltung zum Steuern eines Erregerstromes, der Relaiswicklungen (RC1, RC2, RC3) zugeführt wird, mit einer Referenz-Stromversorgung (1) und einer Niederspannungs-Stromversorgung (3; 30), die eine Spannung niedriger als die gegebene Referenzspannung (V_B) ausgibt, **dadurch gekennzeichnet, daß**

a) die Relaiskontakte (RS1, RS2, RS3) zwischen die Referenzstromversorgung (1) und einer Vielzahl an Lasten (21, 22, 23) platziert sind; und

b) die Niederspannungs-Stromversorgung (3; 30) eine Spannung (V_A) ausgibt, die niedriger ist als die gegebene Referenzspannung (V_B) und höher ist als die Relaisbetätigungsspannung zum Zuführen des Erregerstromes zu jeder Relaiswicklung von der Niederspannungs-

Stromversorgung (3; 30).

2. Relaisreiberschaltung zum Steuern eines Erregerstromes, der Relaiswicklungen (RC1, RC2, RC3) zugeführt wird, mit einer Referenz-Stromversorgung (1) und einer Niederspannungs-Stromversorgung (30), die eine Spannung ausgibt, die niedriger ist als die gegebene Referenzspannung (V_B), **dadurch gekennzeichnet, daß** eine Relaisreiberschaltung vorgesehen ist, die folgendes aufweist:

1) eine Niederspannungs-Stromversorgung (30), die eine Spannung ausgibt, welche niedriger ist als die gegebene Spannung und die höher ist als eine Relais-Freigabespannung;

2) eine Zeitzähleinrichtung (CPU 5) zum Zählen der verstrichenen Zeit seit dem Betätigungszeitpunkt von jedem Relais;

3) eine Speichereinrichtung (ROM 51) zum speichern einer Voreinstell-Zeit (T); und

4) eine Steuereinrichtung zum Zuführen des Erregerstromes von der Referenz-Stromversorgung (1), wenn jedes Relais betätigt wurde, und die den Erregerstrom von der Referenz-Stromversorgung (1) zuführt, bis nach dem Verstreichen der voreingestellten Zeit (T) seit dem Betätigungszeitpunkt von jedem Relais, wobei dann der Erregerstrom von der Niederspannungs-Stromversorgung (30) aus zugeführt wird.

3. Relaisreiberschaltung nach Anspruch 2, bei der die Niederspannungs-Stromversorgung (30) eine Spannung ausgibt, die niedriger ist als die Relais-Betätigungsspannung.

4. Relaisreiberschaltung zum Steuern eines Erregerstromes, der Relaiswicklungen (RC1, RC2, RC3) zugeführt wird, mit einer Referenz-Stromversorgung (1) und mit einer Niederspannungs-Stromversorgung (30), die eine Spannung ausgibt, die niedriger ist als die gegebene Referenzspannung (V_B), **dadurch gekennzeichnet, daß**

eine Relaisreiberschaltung vorgesehen ist, die folgendes aufweist:

1) eine Niederspannungs-Stromversorgung (30), die eine Spannung ausgibt, die niedriger ist als die gegebene Spannung und die höher ist als eine Relaisfreigabespannung; und

2) eine Referenzspannungs-Schaltung (41; Q11, D11, D12, R11, R12, C11) zum Zuführen

eines Erregerstromes zu jeder Relaiswicklung von der Referenz-Stromversorgung;

3) eine Niederspannungs-Schaltung zum Zuführen eines Erregerstromes zu jeder Relaiswicklung von der Niederspannungs-Stromversorgung (30); und

4) eine Anhalte-Steuerschaltung (41; Q11, D11, D12, R11, R12, C11) zum Anhalten der Erregerstromzuführung von der Referenz-Stromversorgung (1) nach dem Verstreichen einer vorbestimmten Zeitdauer seit dem Betätigungszeitpunkt der Relaiskontakte, nach der Zufuhr des Erregerstromes von der Referenz-Stromversorgung (1).

5. Relaisreiberschaltung nach Anspruch 4, bei der die Niederspannungs-Stromversorgung (30) eine Spannung ausgibt, die niedriger ist als die Relaisbetätigungsspannung.

6. Relaisreiberschaltung nach Anspruch 4, bei der die Anhalte-Steuerschaltung einen Kondensator (C11) umfaßt und in der Referenz-Spannungsschaltung eingebaut ist, um in Einklang mit einer vorbestimmten Zeitkonstanten die angelegte Spannung abzusinken und zwar nach der Zufuhr des Erregerstromes durch Anlegen einer Spannung an die Wicklung von der Referenz-Stromversorgung (1).

7. Relaisreiberschaltung zum Steuern eines Erregerstromes, der Relaiswicklungen (RC1, RC2, RC3) zugeführt wird, mit einer Referenz-Stromversorgung (1) und einer Niederspannungs-Stromversorgung (30), die eine Spannung ausgibt, die niedriger liegt als die gegebene Referenzspannung (V_B), **dadurch gekennzeichnet, daß** eine Relaisreiberschaltung vorgesehen ist, die folgendes aufweist:

1) eine Niederspannungs-Stromversorgung (30), die eine Spannung ausgibt, die niedriger ist als die gegebene Spannung und die höher ist als eine Relaisfreigabespannung;

2) eine Referenzspannungs-Schaltung (51; Q111, D111, R111-R113, C111), um periodisch einen Erregerstrom zu jeder Relaiswicklung in der Länge einer voreingestellten Zeitdauer zuzuführen und zwar von der Referenz-Stromversorgung, wenn ein Relaisbetätigungsbefehl gegeben wird; und

3) eine Niederspannungs-Schaltung zum Zuführen eines Erregerstromes zu jeder Relaiswicklung von der Niederspannungs-Stromversorgung (30), wenn ein Relaisbetätigungsbe-

fehl gegeben wird.

8. Relaisreiberschaltung nach Anspruch 7, bei der die Referenz-Spannungsschaltung folgendes aufweist:

eine Oszillatorschaltung (5) zum Ausgeben eines Impulssignals mit einer Impulsbreite der Aufbauzeit bei einer gegebenen Periode; und

eine Spannungs-Versorgungsschaltung zum Zuführen des Erregerstromes von der Referenz-Stromversorgung (1) lediglich dann, während das Impulssignal ausgegeben wird, wenn ein Relaisbetätigungsbefehl gegeben wird.

9. Relaisreiberschaltung nach Anspruch 7, bei der die Niederspannungs-Stromversorgung (30) eine Spannung ausgibt, die niedriger ist als die Relaisbetätigungsspannung.

Revendications

1. Circuit de pilotage de relais pour commander un courant d'excitation qui est appliqué sur des bobines de relais (RC1, RC2, RC3), comprenant une alimentation de référence (1) et une alimentation basse tension (3 ; 30) qui émet en sortie une tension inférieure à la tension de référence donnée (V_B), **caractérisé en ce que :**

a) les contacts de relais (RS1, RS2, RS3) sont placés entre ladite alimentation de référence (1) et une pluralité de charges (21, 22, 23) ; et
b) ladite alimentation basse tension (3 ; 30) émet en sortie une tension (V_A) qui est inférieure à la tension de référence donnée (V_B) et qui est supérieure à la tension d'actionnement de relais pour appliquer le courant d'excitation sur chaque bobine de relais depuis ladite alimentation basse tension (3 ; 30).

2. Circuit de pilotage de relais pour commander un courant d'excitation qui est appliqué sur des bobines de relais (RC1, RC2, RC3), comprenant une alimentation de référence (1) et une alimentation basse tension (30) qui émet en sortie une tension inférieure à la tension de référence donnée (V_B), **caractérisé en ce qu'un circuit de pilotage de relais est prévu, lequel comprend :**

1) une alimentation basse tension (30) qui émet en sortie une tension qui est inférieure à la tension donnée et qui est supérieure à une tension de libération de relais ;

2) un moyen de comptage de temps (CPU 5) pour compter un temps écoulé à partir du temps

d'actionnement de chaque relais ;

3) un moyen de stockage (ROM 51) pour stocker un temps préétabli (T) ; et

4) un moyen de commande pour appliquer le courant d'excitation en provenance de l'alimentation de référence (1) lorsque chaque relais est actionné et pour appliquer le courant d'excitation en provenance de l'alimentation de référence (1) jusqu'à l'expiration du temps préétabli (T) depuis le temps d'actionnement de chaque relais puis pour appliquer le courant d'excitation en provenance de ladite alimentation basse tension (30).

3. Circuit de pilotage de relais selon la revendication 2, dans lequel ladite alimentation basse tension (30) émet en sortie une tension qui est inférieure à la tension d'actionnement de relais.

4. Circuit de pilotage de relais pour commander un courant d'excitation qui est appliqué sur des bobines de relais (RC1, RC2, RC3), comprenant une alimentation de référence (1) et une alimentation basse tension (30) qui émet en sortie une tension inférieure à la tension de référence donnée (V_B), **caractérisé en ce qu'un circuit de pilotage de relais est prévu, lequel comprend :**

1) une alimentation basse tension (30) qui émet en sortie une tension qui est inférieure à la tension donnée et qui est supérieure à une tension de libération de relais ;

2) un circuit de tension de référence (41 ; Q11, D11, D12, R11, R12, C11) pour appliquer un courant d'excitation sur chaque bobine de relais à partir de l'alimentation de référence ;

3) un circuit basse tension pour appliquer un courant d'excitation sur chaque bobine de relais à partir de ladite alimentation basse tension (30); et

4) un circuit de commande d'arrêt (41 ; Q11, D11, D12, R11, R12, C11) pour arrêter l'application du courant d'excitation depuis l'alimentation de référence (1) après l'expiration d'un temps prédéterminé depuis le temps d'actionnement des contacts de relais après l'application du courant d'excitation depuis l'alimentation de référence (1).

5. Circuit de pilotage de relais selon la revendication 4, dans lequel ladite alimentation basse tension (30) émet en sortie une tension qui est inférieure à la tension d'actionnement de relais.

6. Circuit de pilotage de relais selon la revendication 4, dans lequel ledit circuit de commande d'arrêt comprend un condensateur (C11) et est incorporé dans ledit circuit de tension de référence pour

abaisser une tension appliquée conformément à une constante de temps prédéterminée après une application de courant d'excitation au moyen d'une application de tension sur la bobine à partir de l'alimentation de référence (1).

7. Circuit de pilotage de relais pour commander un courant d'excitation qui est appliqué sur des bobines de relais (RC1, RC2, RC3), comprenant une alimentation de référence (1) et une alimentation basse tension (30) qui émet en sortie une tension inférieure à la tension de référence donnée (V_B), **caractérisé en ce qu'un circuit de pilotage de relais est prévu, lequel comprend :**

1) une alimentation basse tension (30) qui émet en sortie une tension qui est inférieure à la tension donnée et qui est supérieure à une tension de libération de relais ;

2) un circuit de tension de référence (51 ; Q111, D111, R111 à R113, C111) pour appliquer de manière périodique un courant d'excitation aussi longtemps qu'un temps préétabli sur chaque bobine de relais à partir de l'alimentation de référence lorsqu'une instruction d'actionnement de relais est appliquée ; et

3) un circuit basse tension pour appliquer un courant d'excitation sur chaque bobine de relais à partir de ladite alimentation basse tension (30) lorsqu'une instruction d'actionnement de relais est produite.

8. Circuit de pilotage de relais selon la revendication 7, dans lequel ledit circuit de tension de référence comprend :

un circuit d'oscillation (5) pour émettre en sortie un signal impulsionnel qui présente une largeur d'impulsion du temps d'instauration sur une période donnée ; et

un circuit d'application de tension pour appliquer le courant d'excitation à partir de l'alimentation de référence (1) seulement tandis que le signal impulsionnel est émis en sortie lorsqu'une instruction d'actionnement de relais est produite.

9. Circuit de pilotage de relais selon la revendication 7, dans lequel ladite alimentation basse tension (30) émet en sortie une tension qui est inférieure à la tension d'actionnement de relais.
